graph theory: study the material

graph programming libraries: analyze and use of programming tools and libraries that work with graphs (Leda, GraphBase, Boost, etc.)

graph visualization: analyze and use of tools to visualize graphs and the information they contain (OGDF, Graphviz, yED, etc.)

applications: search for applications that use graph algorithms or graphs as data structures (e.g., network planification, route optimization)

(日)

- What is a bridge?
- What is a partition?
- What is an independent set?
- What is a bipartite graph?
- What is the time complexity of DFS?

∃ >

graphs can be found, e.g., in the following situations:

- street plans or maps
- networks (data, fluids, traffic etc.)
- transport systems
- chemical connexions in a large molecule
- neighborhood relations in a worldmap
- interference relations between antennas in a wireless communication system
- links between WWW pages
- closeness relation in arrangments

Hence, a graph is an abstract concept behind the representation of relations (edges) between entities (nodes or vertices)

Vocabulary neighborhood

neighbor node	v is neighbor of w , if $vw \in E(v)$,
	i.e., if v and w are adjacent
neighbor edge	<i>e</i> is neighbor of <i>f</i> , if $e \cap f \neq \emptyset$
	i.e., <i>e</i> and <i>f</i> are incident to the same vertex
independent	vertices/edges non adjacent,
	a set of vertices (edges) mutually
	independent is an independent set
complete	a graph is complete,
	if all its vertices are neighbors
partition	the set of set $\{V_0,, V_{r-1}\}$
	is a partition of V ,
	if $V = \bigcup_i V_i$, $V_i \neq \emptyset$, and $\forall i \neq j : V_i \cap V_j = \emptyset$

 $\alpha(G)$ size of the largest independent set of vertices

・ロト ・ 四ト ・ ヨト ・ ヨト

digraph	the edges are directed, i.e.,	
	instead of the sets $\{v, w\}$ we use	
	pairs (v, w) or (w, v)	
	i.e., $E \subseteq V \times V$	
multigraph	permits more than one edge between vertices	
pseudograph	permits loops on vertices	

イロト イヨト イヨト イヨト

A graph can be stored with three basic methods:

- adjacency matrix
 - square matrix, and in the simple case, binary (and symmetric if not digraph) that codes whether there exists an edge between vertices
 - space complexity $\Omega(n^2)$
- adjacency lists
 - list or array of vertices which contain in each entry a list to its adjacent vertices
 - space complexity $\Theta(n+m)$

hashtables

- list or array of vertices which contain in each entry a hashtable to its adjacent vertices
- space complexity $\Theta(n+m)$

What are the principal advantages and disadvantages of each method?

There are more data structures available which are useful to implement certain algorithms more efficiently (especially for planar graphs).

Let G = (V, E) and G' = (V', E') be two graphs.

If there is a bijection $\varphi: V \longrightarrow V'$ between the vertices of the graphs such that

$$xy \in E \iff \varphi(x)\varphi(y) \in E'$$

(i.e., if x and y are neighbors in G, then $\varphi(x)$ and $\varphi(y)$ are neighbors as well in G'),

then *G* is isomorph to G', $G \simeq G'$ or as well G = G', i.e., one can say the graph *G*.

イロト イ押ト イヨト イヨト

A function *f* over two graphs with f(G) = f(G') if $G \simeq G'$ is called invariant. E.g., invariants are:

- n
- m
- Are there more invariants?

No one knows an invariant for graphs which can be computed in deterministic polynomial time which decides whether two graphs are isomorphic, however, it is not demonstrated that the problem is *NP*–complete.

.

Remind what it means *NP*-complete:

A problems belongs to the class of *NP*–complete problems, if there exists deterministic Turing machine (sufficiently powerful computing model) that solves the problem in polynomial time (in respect to input length) and all other problems in the class are at most simpler.

イロト イ押ト イヨト イヨト

Hence we know for *NP*–complete problems:

- There exists an algorithm for solving it. (We can always use exhaustive search.)
- If someone gives us a potential solution, we can verify in polynomial deterministic time that it is really a solution.
- If we would know a polynomial algorithm for any *NP*-complete problem, implicitely we could solve all problems of the class with that time bound.
- Whether the two classes *P* and *NP* are equal is one of the famous open problems in computer science (and most people think they are different).

(二回) (二回) (二回)

Given a bijection between the nodes of two graphs, it is easy to prove whether the graphs are isomorphic: it is sufficient to check whether the adjacency matrices are identical, this can be done in time $O(n^2)$.

Hence, the isomorphism problem is in NP.

Let G = (V, E) and G' = (V', E') be two graphs.

 $G \cup G' := (V \cup V', E \cup E')$ union of the graphs $G \cap G' := (V \cap V', E \cap E')$ intersection of the graphs

イロト イ押ト イヨト イヨト

partial graph	G' is partial graph of G , if $V' \subseteq V$ and $E' \subseteq E$
subgraph	${\it G}'$ is subgraph of ${\it G},$ of ${\it G}'\cap {\it G}={\it G}',$
	i.e., G' is a partial graph of G
	that contains all edges of G
	whose incident vertices are in V' .
induced	for $V' \subseteq V$ the graph $(V', E(V', V'))$
	is the subgraph G' of G induced by V'

イロト イヨト イヨト イヨト

$\begin{array}{ll} G' \subseteq G & G' \text{ is partial graph of } G \\ G[V'] & \text{subgraph of } G \text{ over } V' \text{ assuming } V' \subseteq V \\ G[G'] & \text{subgraph of } G \text{ over } V(G') \text{ assuming } G' \subseteq G \end{array}$

・ロト ・ 同ト ・ ヨト ・ ヨ

r-partite a graph is an *r*-partition, if their exists a partition of *V* defining *r* independent sets
 bipartite 2-partite

イロト イ理ト イヨト イヨト

k-regular graphs complete graphs K^r paths P^k cycles C^k

$$d(G) = \epsilon(G) = k \ (= \delta(G) = \Delta(G))$$

$$G = (V, [V]^2), |V| = r$$

$$G = (\{v_0, \dots, v_k\}, \{v_0v_1, v_1v_2, \dots, v_{k-1}v_k\})$$

$$G = (\{v_0, \dots, v_k\}, \{v_0v_1, v_1v_2, \dots, v_{k-1}v_0\})$$

< 4 →

.

Obviously, one can describe a path or cycle by its node sequence.

length	number of edges of a path or cycle
cyclic	a graph that contains a cycle is cyclic
acyclic	a graph that does not contain a cycle is acyclic
girth	a minimum length cycle of the graph
circumference	a maximum length cycle of the graph

g(G)	length of the girth of G
	$(g(G) = \infty$ if G acyclic)
D(G)	length of the circumference of G
	(D(G) = 0 if G acyclic)

イロト イヨト イヨト イヨト

- bipartite graphs B
- bipartite complete graphs K^{n_1,n_2}
- hypercubes Q^k properties (with exceptions for Q^0 and Q^1):

•
$$n = |V| = 2^k$$

- k-regular
- bipartites (How to partition?)
- $g(Q^k) = 4$
- $D(Q^k) = 2^k$ (What is a maximum cycle?)
- $\alpha(Q^k) = 2^{k-1}$ (and there are two)

d(v, w) distance between two vertices being the length of the shortest path between v and w $d_G(v, w)$ distance between v and w in G

The distance defines a metric, i.e.,

$$f(v,w) \ge 0$$

$$d(v,w) = d(w,v)$$

$$d(u,w) \leq d(u,v) + d(v,w)$$

connected	v and w are connected, if $d(v, w) < \infty$; G is connected,
	if all pairs $\{v, w\} \subset V$ are connected
unconnected	G is unconnected if it is not connected
bridge	edge $e \in G$ is a bridge if
	<i>G</i> is connected but $G \setminus e$ is unconnected
cut vertex	vertex $v \in G$ if
	G connected but $G \setminus v$ is unconnected
connected components	connected and maximum subgraphs

イロト イヨト イヨト イヨト

- c(G) number of connected components of G
- $\kappa(G)$ minimum size of vertex subset of *G* such that $G \setminus V$ is unconnected
- $\lambda(G)$ minimum size of edge subset of G such that $G \setminus E$ is unconnected

k–connected biconnected *k*–edgeconnected block *G* is *k*–connected, if $\kappa(G) \ge k$ 2–connected *G* is *k*–edgeconnected, if $\lambda(G) \ge k$ maximum biconnected subgraph

★ ∃ →

- if G does not contain cycles, G is a forest
- if G is a forest and connected, G is a tree
- the connected components of a forest are trees

trees

Theorem

the following properties are equivalent:

- G is a tree
- between edge pair of vertices there exists exactly one path
- each edge is a bridge
- G is acyclic and n = m 1
- G is connected and n = m 1
- G is acyclic and maximum in |E|
- G is connected and minimum in |E|

free tree rooted tree spanning tree a tree where no vertex is marked a tree with one vertex marked as root T is spanning tree of a graph G, if $T \subseteq G$ and V(T) = V(G)

Theorem

each graph G contains a spanning forest, and if G is connected, it contains a spanning tree (with any vertex as root)

euler walk	path between two vertices
	that does not visit more than once
	an edge
euler graph	graph with euler walk
	using all its edges
hamilton graph	graph with path (cycle) over all its vertices

Theorem (WHITNEY)

 $\textit{G is biconnected (|G| > 2)} \quad \Longrightarrow \quad \forall v, w \in V \exists v P w, v Q w : P \cap Q = \emptyset$

i.e., there exist always two paths that do not intersect (for all possible pairs of vertices in G)

Theorem (MADER)

each graph G with mean number of edges $\epsilon(G) \ge 4k$ contains a *k*-connected graph as partial subgraph

Algorithms

Algorithm

Depth first search

DFS generates a rooted tree T with back–edges (that do not belong to T). DFS serves, for examples, to

- determine connected components
- detect bridges
- detect cut vertices
- detect blocks
- sort topologically

Let T be a tree of a connected graph G with v as root generated by DFS.

v is a cut vertex $\iff v$ has more then one son in T

Theorem

Let T be a tree of a connected graph G generated by DFS and v not its root.

v is a cut vertex \iff there does not exist a back–edges from the subtree below v towards an predecesor of v in T

```
DFS has complexity \Theta(n + m) (assuming adjacency lists, and with the other storing possibilities?)
```

Algorithm

breadth first search

BFS generates a rooted tree T with back–edges and cross–edges. BFS serves, for example, to:

- determine the shortest paths between vertices
- sort topological

BFS has complexity $\Theta(n+m)$

(assuming adjacency lists, and with the other storing possibilities?)

.

Let *G* be a graph and let \overline{G} be a directed graph (digraph).

strongly connected	\overline{G} is strongly connected, if there exists a walk
	between each pair of vertices de G
orientable	G is orientable,
	if there exists a graph $\overline{G}\simeq G$
	that is strongly connected
strongly connected	
component	maximum set of vertices of \overline{G} whose induced subgraph is strongly connected

center the center of a graph *G* is the subgraph of *G* induced by the vertices with minimum excentricity median the median of a graph *G* is the subgraph of *G* induced by the vertices with minimum total distance

- B → - 4 B

$$G \text{ connected} \implies \operatorname{rad}(G) \leq \operatorname{diam}(G) \leq 2 \cdot \operatorname{rad}(G)$$

Theorem

Every graph is the center of a graph.

Theorem

The center of a tree consists of one or two vertices.

Algorithm to calculate the center of a tree?

-∢ ∃ ▶

given a weighted graph G (or a digraph \overline{G}) interesting questions are:

- What is the minimum spanning forest for G?
- given a vertex $s \in \overline{G}$, What are the minimum paths to all other vertices?
- What are the minimum paths among all pairs of vertices?

★ ∃ →

- To each vertex $u \in G$ there exists a shortest path from *s*.
- The paths to all vertices along the path are shortest paths as well.
- If G is connected, we can construct a tree with root s ∈ G which deternines all shortest paths to the other vertices in the graph.
- Algorithm that calculates a minimum forest of a graph G?

Algorithm

KRUSKAL, join greedily trees with minimum edges, complexity $O(m \log n)$

Algorithm

PRIM, construct iteratively a tree with minimum edges, complexity $O(m + n \log n)$

< ロ > < 同 > < 回 > < 回 >

Algorithm that computes a minimum tree starting at a vertex s in \overline{G} ?

Algorithm

DIJKSTRA, complexity $O(n^2)$

The algorithm works equally with graphs and with digraphs.

One can permit negative weights?

There might exist negative cycles.

Algorithm that calculates a mimimum tree starting at a vertex s en G if G contains negative weights?

Algorithm

BELLMANN–FORD, complexity *O*(*mn*)

Algorithm that calculates the minimum paths between all pairs of vertices including the case of negative weights?

Algorithm

FLOYD–WARSHALL, complexity $O(n^3)$

Some algorithms detect negative cycles in which case they simply stop.

if we have more information over the graph and its weights we can improve the algorithms:

- if the weights are confined by a constant *W*:
- if the number of edges *m* is confined by *O*(*n* log *n*):

★ ∃ →

- contraction of edges
- minor
- topological minor

イロト イポト イヨト イヨ

Consequence:

Theorem (ROBERTSON/SEYMOUR)

Each heritable property over graphs can be represented by a finite number of prohibited minors.

・ロト ・ 同ト ・ ヨト ・ ヨ

There are interesting questions how certain properties of graphs are related to the size of the graph (normally number of edges in relation to number of nodes).

- How many edges a graph must have as minimum such that it is connected?
- How many edges a graph can hve as maximum such that it is planar?

planar	a graph is planar if we paint its vertices and its edges in the plane such that
	•
	no pair of edges crosses
region	a region is an area of the plane
	where we have painted a planar graph
	that is surrounded by edges
triangular graph	a graph is triangular,
	if in its planar representation
	all regiones are triangles

イロト イヨト イヨト イヨト

Theorems planarity

Theorem (EULER)

G is planar and connected with $n \le 1$, m and $l \implies n - m + l = 2$

Theorem

G planar with $n \ge 3 \implies m \le 3n - 6$

Theorem

G maximum planar if it is a triangular graph (and contains 3n - 6 edges)

Theorem (KURATOWSKI)

G is planar \iff does not contain a K^5 or a $K^{3,3}$ as minor (or topological minor)

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

- Coloring of vertices
- Coloring of edges
- Coloring of planar graphs

A (10) > A (10) > A (10)

G planar \implies the vertices of G can be colored with 4 colors

Theorem

G planar with no triangle \implies the vertices of G can be colored with 3 colors

 $\begin{array}{ll} \chi(G) & \mbox{minimum number of colors needed} \\ & \mbox{to color the vertices of a graph} \\ \chi'(G) & \mbox{minimum number of colors needed} \\ & \mbox{to color the edges of a graph} \\ \chi''(G) & \mbox{minimum number of colors needed} \\ & \mbox{to color the vertices and the edges of a graph} \end{array}$

- A 🖻 🕨

Theorem (BROOKS)

G connected $G \neq C^{impar}$ and $G \neq K^n \implies \chi(G) \leq \Delta(G)$

Theorem (KOENIG)

G bipartite $\implies \chi'(G) = \Delta(G)$
